#### Abstract

The traditional sieve of Eratosthenes gives a simple algorithm for finding all prime numbers. However, prime numbers seem appear unpredictably but with regular population ratio in the ranges of integers, as Gauss found a density function of prime numbers within a range of $x$. On the other hand, there are a few methods of classification of prime numbers. We developed a new classification of prime numbers by prime number trees. In the prime number trees, the followed number is generated by attaching a digit either $1,3,7$, or 9 to the right hand side of the preceding prime number. If the number generated remains prime, then the process is continued, otherwise it is stopped. The prime number trees group prime numbers with similar digits together and show the elegancy of a shorthand of prime numbers. This method also shows a regular classification of prime numbers.

## Part A. Prime Number Trees in the Decimal Number System

## 1. Introduction

### 1.1. Prime numbers

The traditional sieve of Eratosthenes gives a simple algorithm for finding all prime numbers. However, prime numbers seem appear unpredictably but with regular population ratio in the ranges of integers, as Gauss found the density function of prime numbers within a range of $x$ to be $\approx \frac{1}{\ln x}$ [2]. On the other hand, there are a few methods of classification of prime numbers. This is probably due to the lack of understanding the properties of prime numbers. No formulae has been found
to compute prime numbers successfully. For example, Fermat numbers, Mersenne numbers are not all prime. Fermat Little Theorem only gives the property of prime numbers but not a method of inspecting a number to be prime.

### 1.2. Classification of Prime Numbers

According to Erdős -Selfridge's classification of prime numbers [1], there are infinite classes of prime numbers with each class containing infinite prime numbers. In each class, there is not a clear regulation of appearing of prime numbers. This is shown in Chapter 2.

We developed a new classification of prime numbers by prime number trees. In the prime number trees, the followed number is generated by attaching a digit either $1,3,7$, or 9 to the right hand side of the preceding prime number. If the number generated remains prime, then the process is continued, otherwise it is stopped. For example, the prime number tree of 2 contains $2,23,233,2333,23333$, which are all prime. The prime number trees group prime numbers with similar digits together and show the elegancy of a shorthand of prime numbers. This method also shows a regular classification of prime numbers.

## 2. Traditional Classification of Prime Numbers

### 2.1. Erdős -Selfridge's Classification of Prime Numbers

Paul Erdős and John Selfridge classified prime numbers as follows. For $p$ to be a prime number,
(i) if the largest prime factor of $p+1$ is 2 or 3 , then $p$ is in Class 1 ,
(ii) if the largest prime factor of $p+1$ is in class $c$, then p is in Class $(c+1)$.

### 2.2. Classes of Prime Numbers

Class 1: $2,3,5,7,11,17,23,31,47,53,71,107,127,191,383, \ldots$
e.g. For the prime number $p=3, p+1=4=2 \times 2$, the largest prime factor of $(p+1)$ is 2 . Then $p=3$ is in Class 1 .

For the prime number $p=5, p+1=6=2 \times 3$, the largest prime factor of $(p+1)$ is 3 . Then $p=5$ is in Class 1 .

Prime numbers in Class 1 are of the form $2^{i} 3^{j}-1$ for $i \geq 0$ and $j \geq 0$.

Class 2: $13,19,29,41,43,59,61,67,79,83,89,97,101,109,131$, 137, 139, ...
e.g. For the prime number $p=13, p+1=14=2 \times 7$, the largest prime factor of $(p+1)$ is 7 , which is in Class 1. Then $p=13$ is in Class 2.

Class 3: 37, 103, 113, 151, 157, 163, 173, 181, 193, 227, 233, 257, 277, 311, 331, 337, ...
e.g. For the prime number $p=37, p+1=38=2 \times 19$, the largest prime factor of $(p+1)$ is 19 , which is in Class 2 . Then $p=37$ is in Class 3.

Class 4: 73, 313, 443, 617, 661, 673, 677, 691, 739, 757, 823, 887, 907, 941 ...
e.g. For the prime number $p=73, p+1=74=2 \times 37$, the largest prime factor of $(p+1)$ is 37 , which is in Class 3 . Then $p=37$ is in Class 4.

Therefore, the Erdős-Selfridge classification of primes classifies prime numbers according to their neighbours.

## 3. Classification of Prime Numbers by Prime Number Trees

### 3.1. Prime Number Trees

The Prime Number Tree is a sequence or a family of prime numbers. It starts from a prime number and ends again with a prime number. In a prime number tree, the followed number is generated by attaching $1,3,7$ or 9 to the right hand side of the preceding prime number and it remains prime. The sequence ends when no more prime number can be generated by doing so. e.g. $2,23,233,2333,23333$ are all prime. However, 233331, 233333, 233337 and 233339 are no longer prime. The prime number tree of 2 is shown below.

| First prime number | $1^{\text {st }}$ digit | $2^{\text {nd }}$ digit | $3^{\text {rd }}$ digit | $4^{\text {th }}$ digit | $5^{\text {th }}$ digit | $6^{\text {til }}$ digit | $7^{\text {th }}$ digit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| (2) | (3) <br> (9) | (3) <br> (9) <br> (3) | (3) <br> (9) <br> (3) <br> (9) <br> (9) | (3) <br> (9) <br> (9) <br> (3) <br> (9) | (3) <br> (3) <br> (9) | (3) <br> (3) <br> (9) | (9) <br> (9) |

Table 1. Prime Number Tree of 2. The prime number tree ends when no more prime number can be generated.

Definition 1. Scheme of Odd Unit Integers Plus Multiple of Ten (SOUIPMT) If a new prime number is produced by multiplying an old prime number by 10 and followed by an addition of either 1, 3, 7 or 9, this new prime number is said to be generated by the Scheme of Odd Unit Integers Plus Multiple of Ten (SOUIPMT).
e.g. $p_{1}=2$ is prime, $p_{2}=10 \times 2+3=23$ is also prime. $p_{2}$ is said to be generated by SOUIPMT.

Definition 2. Fundamental Prime Number A fundamental prime number is a prime number which cannot be generated by SOUI $\overline{P M T}$.
e.g. The prime number $23=10 \times 2+3$. It can be generated by SOUIPMT. Therefore, 23 is not a fundamental prime number.
e.g. The prime number $89=10 \times 8+9$. Since 8 is not prime, 89 cannot be generated by SOUIPMT. Therefore, 89 is a fundamental prime number.

Definition 3. Tail Prime Number $A$ tail prime number is a prime number which cannot generate a new prime number by SOUIPMT.
e.g. 23333 is prime. However, 233331, 233333, 233337, 233339 are all composite. Therefore, 23333 is a tail prime number.

Definition 4. Prime Number Tree A prime number tree is composed of prime number sequences which start from the same fundamental prime number and the followed prime numbers generated by SOUIPMT, one by one. The sequences end with different tail prime numbers so that there are many branches in it.

The prime number trees of 3,5 and 7 are shown below.

| $\begin{array}{\|c\|} \hline \text { First prime } \\ \text { number } \end{array}$ | $1^{\text {st }}$ digit | $2^{\text {nd }}$ digit | $3^{\text {rd }}$ digit | $4^{\text {th }}$ digit | $5^{\text {th }}$ digit | $6^{\text {thl }}$ digit | $7^{\text {th }}$ digit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| (3) |  | (1) <br> (3) <br> (7) <br> (3) <br> (9) | (9) <br> (7) <br> (3) <br> (9) <br> (3) <br> (7) | (3) <br> (9) <br> (7) <br> (9) <br> (7) | (9) <br> (3) | (9) | (9) |

|  | (9) | (3) <br> (9) | (3) <br> (3) | (3) | (9) |

Table 3. Prime Number Tree of 5

Table 4. Prime Number Tree of 7
Definition 5. Alone Prime Number An alone prime number is a prime number tree containing only the fundamental prime number. The fundamental prime number is also the tail prime number.

A list of alone prime numbers is shown in Table 5 below.

| 89 | 389 |
| :--- | :--- |
| 107 | 443 |
| 167 | 457 |
| 251 | 461 |

Table 5. Alone prime numbers

### 3.2. Properties of Tail Prime Numbers

For tail prime numbers or alone prime numbers $p$, particularly with $p \equiv 2(\bmod 3)$, we can construct four composite numbers as $q_{1}=10 p+1, q_{2}=10 p+3, q_{3}=10 p+7$ and $q_{4}=10 p+9$ such that

$$
\left\{\begin{array}{l}
10 p+1=p_{1} \times n_{1} \\
10 p+3=p_{2} \times n_{2} \\
10 p+7=p_{3} \times n_{3} \\
10 p+9=p_{4} \times n_{4}
\end{array}\right.
$$

where $p_{1}, p_{2}, p_{3}$ and $p_{4}$ are the smallest odd prime factors whereas $n_{1}, n_{2}, n_{3}$ and $n_{4}$ are odd positive integers greater than 1 . It is found that $q_{3}-q_{1}=6$ and

$$
\begin{equation*}
p_{3} \times n_{3}-p_{1} \times n_{1}=6 \tag{1}
\end{equation*}
$$

which is an indefinite linear Diophantine equation with conditions $10 p+1=p_{1} \times n_{1}$ and $10 p+7=p_{3} \times n_{3}$. The solution to the equation (1) can be found as $p_{3}=p_{1}=3$ and $n_{3}-n_{1}=2$. Hence $q_{1}=10 p+1=3 n_{1}$, which is a multiple of 3 .

In this case there are two remarks.

1. For $p$ to be a tail prime number and $p \equiv 1(\bmod 3)$, it does not imply the solution to equation (1) is $p_{3}=p_{1}=3$ and $n_{3}-n_{1}=2$. The counter-example is the tail prime number $p=3793$ with $37931 \equiv 2(\bmod 3), 37937 \equiv 2$ $(\bmod 3), 37933 \equiv 0(\bmod 7)$ and $37939 \equiv 0(\bmod 11)$.
2. If the results $p_{3}=p_{1}=3$ and $n_{3}-n_{1}=2$ are given and with the same condition, it does not imply $p$ must be prime. $q=2009$ is a counterexample. $20091,20093,20097$ and 20099 are all composite and $20091 \equiv 0$ $(\bmod 3), 20097 \equiv 0(\bmod 3)$. However, 2009 is not prime.

Theorem 6. Theorem of Tail Prime Number Let $p$ be a tail prime number with $p \equiv 2(\bmod 3)$. Then $q_{1}=10 p+1, q_{2}=10 p+3, q_{3}=10 p+7$ and $q_{4}=10 p+9$ all are odd composite numbers by the definition of tail prime number. Let

$$
\left\{\begin{array}{l}
10 p+1=p_{1} \times n_{1} \\
10 p+3=p_{2} \times n_{2} \\
10 p+7=p_{3} \times n_{3} \\
10 p+9=p_{4} \times n_{4}
\end{array}\right.
$$

where $p_{1}, p_{2}, p_{3}$ and $p_{4}$ are the smallest odd prime factors whereas $n_{1}, n_{2}, n_{3}$ and $n_{4}$ are odd positive integers. Then $q_{3}-q_{1}=6=p_{3} \times n_{3}-p_{1} \times n_{1}$. The solution to the equation is if and only if $p_{3}=p_{1}=3$ and $n_{3}-n_{1}=2$.
[See reviewer's comment (2)]

Proof. We prove "if" first [See reviewer's comment (3)]. For $p \equiv 2(\bmod 3)$ and $10 p+1=p_{1} \times n_{1}, p_{1} \times n_{1} \equiv 10 p+1(\bmod 3)$. Since $10 p+1 \equiv 1 \cdot p+1 \equiv 1 \cdot 2+1 \equiv 0$ $(\bmod 3), p_{1} \times n_{1} \equiv 0(\bmod 3)$. It is either $p_{1} \equiv 0(\bmod 3)$ or $n_{1} \equiv 0(\bmod 3)$. Similarly, $p_{3} \times n_{3} \equiv 10 p+7 \equiv 1 \cdot p+1 \equiv 1 \cdot 2+1 \equiv 0(\bmod 3)$. It is either $p_{3} \equiv 0$ $(\bmod 3)$ or $n_{3} \equiv 0(\bmod 3)$. Since $p_{1}$ and $p_{3}$ are the smallest odd prime factors, $p_{3}=p_{1}=3 . q_{3}-q_{1}=6=p_{3} \times n_{3}-p_{1} \times n_{1}=3\left(n_{3}-n_{1}\right)$. Then $n_{3}-n_{1}=2$.

We then prove "only if" [See reviewer's comment (4)]. When $p_{3}=p_{1}=3$ and $n_{3}-n_{1}=2, p_{3} \times n_{3}-p_{1} \times n_{1}=3\left(n_{3}-n_{1}\right)=3(2)=6$.

Since alone prime numbers are tail prime numbers, they also satisfy Theorem 6 . Some tail prime numbers with their factorizations are shown below in Table 6.

| Tail prime number | $\begin{gathered} \text { Number } \\ \text { generated by } \\ \text { SOUIPMT } \end{gathered}$ | Smallest prime factor | Other factor |
| :---: | :---: | :---: | :---: |
| $53 \equiv 2(\bmod 3)$ | 531 | 3 | 177 |
|  | 533 | 13 | 41 |
|  | 537 | 3 | 179 |
|  | 539 | 7 | 77 |
| $89 \equiv 2(\bmod 3)^{+}$ | 891 | 3 | 297 |
|  | 893 | 19 | 47 |
|  | 897 | 3 | 299 |
|  | 899 | 29 | 31 |
| $107 \equiv 2(\bmod 3)^{+}$ | 1071 | 3 | 357 |
|  | 1073 | 29 | 37 |
|  | 1077 | 3 | 359 |
|  | 1079 | 13 | 83 |
| $113 \equiv 2(\bmod 3)$ | 1131 | 3 | 377 |
|  | 1133 | 11 | 103 |
|  | 1137 | 3 | 379 |
|  | 1139 | 17 | 67 |
| $167 \equiv 2(\bmod 3)^{+}$ | 1671 | 3 | 557 |
|  | 1673 | 7 | 239 |
|  | 1677 | 3 | 559 |
|  | 1679 | 23 | 73 |
| $179 \equiv 2(\bmod 3)$ | 1791 | 3 | 597 |
|  | 1793 | 11 | 163 |
|  | 1797 | 3 | 599 |
|  | 1799 | 7 | 257 |
| $251 \equiv 2(\bmod 3)^{+}$ | 2511 | 3 | 837 |
|  | 2513 | 7 | 359 |
|  | 2517 | 3 | 839 |
|  | 2519 | 11 | 229 |

Table 6. For every alone prime number $p$ with $p \equiv 2$ $(\bmod 3), 10 p+7$ and $10 p+1$ have a common prime factor 3 and the difference of their remaining factors is $2 . "+$ " means that the tail prime number is also an alone prime number.

## Definition 7. Prime Number Tree Branch

Define prime number tree branch

$$
\left[p ; d_{1} d_{2} d_{3} \ldots d_{n-1} d_{n}\right] \equiv\left\{p, \overline{p d_{1}}, \overline{p d_{1} d_{2}}, \ldots, \overline{p d_{1} d_{2} \ldots d_{n-1}}, \overline{p d_{1} d_{2} \ldots d_{n-1} d_{n}}\right\}
$$

where $p$ is a fundamental prime number, $d_{i}$ 's are either 1, 3, 7 or 9. All set elements are prime.

In a prime number tree, prime number tree branches are prime number sequences starting with the same fundamental prime number but ending with different tail prime numbers. There are many branches in a prime number tree.

In Table 1 , the prime number tree of 2 contains six branches, i.e.
[2;3333],
[2;3339],
[2;3399339],
[2;393],
[2;399333], and
[2;9399999].
2 is the fundamental prime number whereas 23333, 23339, 23399339, 2393, 2399333 and 29399999 all are tail prime numbers.

Definition 8. Length of Prime Number Tree The length of a prime number tree is defined as the number of primes in the longest branch of the prime number tree. Let the longest branch be $\left[p ; d_{1} d_{2} d_{3} \ldots d_{n-1} d_{n}\right]$, where $p$ is a fundamental prime number, and $d_{i}$ 's are either 1, 3, 7 or 9. The branch contains $n+1$ prime numbers. The length of the prime number tree is defined as $L=n+1$.
e.g. In the prime number tree of 2 , the longest branches are [2;3399339] and [2;9399999]. They both contain 8 prime numbers. The length of the prime number tree of 2 is defined as 8 .

Theorem 9. Classification of Prime Numbers by Prime Number Trees Prime number trees give a complete classification of all prime numbers.

Proof. $p$ is a prime number. Suppose it is a fundamental prime number in the decimal number system, $p=\overline{d_{1} d_{2} d_{3} \ldots d_{n}}$, where $d_{i}$ 's are either $0,1,2,3, \ldots, 8$, or 9 , which are unit decimal integers, for $i=1$ to $n$, and $d_{i} \neq 0$. The final digit $d_{n}$ is either $1,3,7$ or 9 . Then $p$ must produce a prime number tree by SOUIPMT and $p$ is in it.

If $p$ is not the fundamental prime number, there exists integers $k$ and $f, k \geq f \geq 1$, $p=10 \times \overline{d_{1} d_{2} d_{3} \ldots d_{f} d_{f+1} \ldots d_{k}}+u$, where $d_{f+1}$ to $d_{k}$ and $u$ are either $1,3,7$ or $9, \overline{d_{1} d_{2} d_{3} \ldots d_{f}}$ is a fundamental prime number defined similar to the above. $p$ is then belonged to the prime number tree of $\overline{d_{1} d_{2} d_{3} \ldots d_{f}}$. Therefore, prime number trees contain and classify all prime numbers in the decimal number system.

Theorem 10. Uniqueness of Prime Numbers in Prime Number Trees Every prime number belongs to a unique prime number tree and prime number trees do not intersect.

Proof. Suppose $p$ is prime. If $p$ is an alone prime number, then it is unique. If $p$ is not an alone prime number, suppose it belongs to two different prime number trees. Let $p=10 \times \overline{p_{1} d_{1} d_{2} \ldots d_{k}}+u$ and $p=10 \times \overline{p_{2} e_{1} e_{2} \ldots e_{m}}+u$, where $k$ and $m$ are some positive integers, $u, d_{1}$ to $d_{k}, e_{1}$ to $e_{m}$ are either $1,3,7$, or $9, p_{1}$ and $p_{2}$ are different fundamental prime numbers. Then

$$
\begin{aligned}
0 & =p-p=\left(10 \times \overline{p_{1} d_{1} d_{2} \ldots d_{k}}+u\right)-\left(10 \times \overline{p_{2} e_{1} e_{2} \ldots e_{m}}+u\right), \\
0 & =10 \times\left(\overline{p_{1} d_{1} d_{2} \ldots d_{k}}-\overline{p_{2} e_{1} e_{2} \ldots e_{m}}\right), \\
\overline{p_{1} d_{1} d_{2} \ldots d_{k}} & =\overline{p_{2} e_{1} e_{2} \ldots e_{m}} .
\end{aligned}
$$

Contradiction! Therefore, $p_{1}=p_{2}, m=k, d_{i}=e_{i}$ for $i=1$ to $k$. Thus $p$ belongs to a unique prime number tree. Since every prime number $p$ belongs to a unique prime number tree, prime number trees do not intersect.

Conjecture 11. Finite Length of Prime Number Trees There is no prime number tree with infinite length.

For every fundamental prime number $p_{h}=\overline{h_{1} h_{2} \ldots h_{m}}$ for some positive integer $m$, it is believed there exists a tail prime number $p_{t}=\overline{h_{1} h_{2} \ldots h_{m} d_{1} d_{2} d_{3} \ldots d_{n}}$, for some positive integer $n$, generated by SOUIPMT, in the longest prime number tree branch, in every prime number tree such that

$$
\begin{aligned}
& 10 \times \overline{h_{1} h_{2} \ldots h_{m} d_{1} d_{2} d_{3} \ldots d_{n}}+1, \\
& 10 \times \overline{h_{1} h_{2} \ldots h_{m} d_{1} d_{2} d_{3} \ldots d_{n}}+3, \\
& 10 \times \overline{h_{1} h_{2} \ldots h_{m} d_{1} d_{2} d_{3} \ldots d_{n}}+7 \text { and } \\
& 10 \times \overline{h_{1} h_{2} \ldots h_{m} d_{1} d_{2} d_{3} \ldots d_{n}}+9
\end{aligned}
$$

all are composite. The length of the prime number tree is $n+1$, which is believed to be finite.

## Part B. Prime Number Trees in the Binary Number System

## 4. Binary Prime Number Trees

### 4.1. Binary Prime Number Trees

Let $p$ be a prime number in the binary number system. e.g. $p=2=10_{(2)}$. Similar to the prime number trees in the decimal number system shown in Part A, the prime number trees in the binary number system are also found and the length of the binary prime number trees can be proved to be finite. Alone binary prime number trees are significantly increased in amount.

Definition 12. Prime Number Tree in the Binary Number System A prime number tree in the binary number system is a sequence of prime numbers. The sequence starts from a fundamental prime number. The following prime numbers are generated by attaching the digit 1 to the right hand side of the preceding prime number. The sequence ends at the tail prime number which cannot generate next prime number.

The number generated by attaching the digit 0 to the right hand side of the preceding prime number must be even and non-prime so that this option is excluded.
e.g. $\quad 10_{(2)}=2,101_{(2)}=5,1011_{(2)}=11,10111_{(2)}=23,101111_{(2)}=47$ are all prime but $1011111_{(2)}=95$ is composite.

Some binary prime number trees are shown below.
(i) Prime number tree of $10_{(2)}=2$

$$
[10 ; 1111]_{(2)}=\left\{10_{(2)}, 101_{(2)}, 1011_{(2)}, 10111_{(2)}, 101111_{(2)}\right\}
$$

(ii) Prime number tree of $11_{(2)}=3$

$$
[11 ; 1]_{(2)}=\left\{11_{(2)}, 111_{(2)}\right\}
$$

(iii) Prime number tree of $1101_{(2)}=13$
$[1101 ;]_{(2)}=\left\{1101_{(2)}\right\}$ which is alone.

Details of binary prime number trees of 2 to 97 are listed in the Table 7 below.

| Prime Number in Binary Number System | Binary Prime Number Trees |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $10_{(2)}=2$ | ${ }^{101}{ }_{(2)}=5$ | ${ }^{1011}(2)=11$ | $10111_{(2)}=23$ | $101111_{(2)}=47$ |  |

Table 7. Binary prime number trees of 2 to 97 . "(alone)" means it is an alone binary prime number tree. "*" means it is included in a preceding binary prime number tree.

### 4.2. Finite Length of Binary Prime Number Trees

The length of decimal prime number trees is not yet known to be finite or infinite. It is probably to be finite by inspecting the prime number trees we worked out, even the amount of prime number trees is still a small number. However, in the binary number system we can prove that the length of binary prime number trees to be finite easily.
Theorem 13. (Fermat Little Theorem) Let $p$ be a prime, and let $a$ be any number with $a \not \equiv 0(\bmod p)$, then $a^{p-1} \equiv 1(\bmod p)$.

We skipped the proof since it is a well-known theorem and it can be found easily in textbooks such as J. H. Silverman's book [3].

Theorem 14. (Theorem of Finite Length of Binary Prime Number Trees) The length of every binary prime number tree is finite.

Proof. Let $p$ be a fundamental prime number in the binary number system. Construct a binary number $q$ by attaching $(p-1)$ digits of 1 to the right hand side of p. i.e.

$$
\begin{aligned}
& q=\bar{p}_{(p-1) 1 s}^{111 \ldots 11}(2), \\
& q=p \times 2^{p-1}+\left(2^{p-2}+2^{p-3}+\cdots+2+1\right)=p \times 2^{p-1}+\frac{2^{p-1}-1}{2-1}, \\
& q=p \times 2^{p-1}+2^{p-1}-1 .
\end{aligned}
$$

By Theorem 13 (Fermat Little Theorem), $2^{p-1} \equiv 1(\bmod p)$. Let $2^{p-1}=p \cdot h$ for some positive integer $h$. Then

$$
q=p \times 2^{p-1}+p \cdot h=p\left(2^{p-1}+h\right)
$$

$q$ is divisible by $p$. Hence $q$ is composite. According to Definition 8 of the length of a prime number tree, let $L$ be the length of the binary prime number tree of $q$, $L \leq p$. Then the length of the binary prime number tree is finite. This applies to every binary prime number tree.

### 4.3. Prime Number Trees in the Ternary Number System

The first few prime numbers in the ternary number system is

$$
2=2_{(3)}, 3=10_{(3)}, 5=12_{(3)}, 7=21_{(3)}, \ldots
$$

We are interested in the length of prime number trees in the ternary number system. Cases of ternary prime number trees are shown below.

Case (I) $p=2_{(3)}=2$.
$20_{(3)}$ and $22_{(3)}$ are even. $21_{(3)}=7$ is prime, which is included in Case (III).
Case (II) $p=10_{(3)}=3$.
$100_{(3)}, 101_{(3)}$ are composite, $102_{(3)}=11$ is prime, which is included in Case (III).

Case (III) $p \geq 12_{(3)}=5$.
In this case, $p \geq 12_{(3)}=5$ and $p$ is odd.
$\overline{p 0_{(3)}}=3 \times p$ is composite. $\overline{p 1_{(3)}}=3 \times p+1$ is even and then composite.
$\overline{p 2_{(3)}}=3 \times p+2$ is odd. Construct a ternary number $q$ by attaching $(p-1)$ digits of 2 to the right hand side of $p$. Note that such a ternary number $q$ is always odd. We then have to apply Fermat Little Theorem to find out its odd-even parity.

$$
\begin{aligned}
q & =\overline{p \underbrace{22 \ldots 22}_{(p-1) 2 s}}(3) \\
& =p \times 3^{p-1}+\left(3^{p-2}+3^{p-3}+\cdots+3+1\right) \\
& =p \times 3^{p-1}+\frac{3^{p-1}-1}{3-1} .
\end{aligned}
$$

By Fermat Little Theorem, $3^{p-1} \equiv 1(\bmod p)$ for $p \geq 5$. Let $3^{p-1}-1=p$, for some positive integer $w$. Since $3^{p-1}-1$ is even and $p$ is odd, $w$ is even.

$$
q=\overline{p \underbrace{22 \ldots 22}_{(p-1) 2 s}}(3)=p \times 3^{p-1}+\frac{1}{2}(p \cdot w),
$$

which is divisible by p and then $q$ is composite.
Hence, in this case, a ternary prime number tree starting from a fundamental prime number $p \geq 12_{(3)}=5$ must be finite in length.

From cases (I), (II) and (III), we conclude that the length of every ternary prime number tree is finite.

We hope the various concepts in prime number trees can give some insights to the understanding of prime numbers.

## Reviewer's Comments

The presentation of this paper is very good. The following is a list of corrections and stylistic suggestions.

1 The reviewer has comments on the wordings, which have been amended in this paper.
2 "The solution to the equation is if and only if" should be rewritten as "The equation has a unique solution".
3 "We prove "if" first" should be deleted.
4 "We then prove "only if"." should be deleted.
